

A photograph showing two people in a field of tall grass. One person is kneeling and operating a piece of equipment, while the other is sitting nearby. A long, thin, white tube is connected to the equipment and extends across the field. In the background, there are trees and a building under a cloudy sky. The image is framed by dark blue vertical bars on the left and right sides.

# THE NEED FOR RELIABLE GAS EMISSION MEASUREMENTS IN THE AGRICULTURAL SECTOR

# CONTENT OF PRESENTATION

---

Focus: Emissions from manure management – NH<sub>3</sub>, GHG (VOC and H<sub>2</sub>S)

- From global to local trends and regulatory incentives
- Source categories of importance
- Challenges in agricultural emission measurements
- Requirements for measurement methods and equipment (protocols)

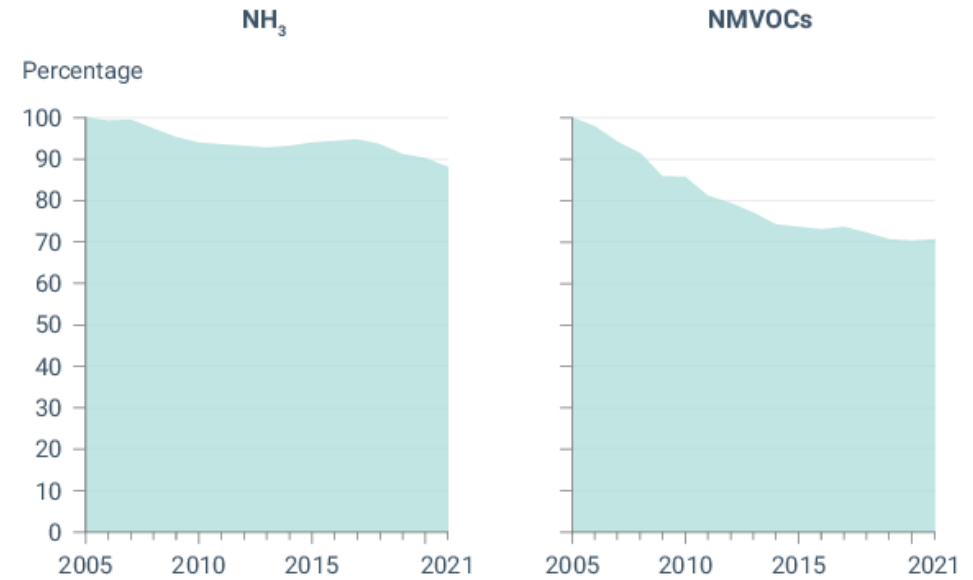

# GLOBAL/EU TRENDS IN AGRO-EMISSIONS

- EU: Despite emission reduction targets, agricultural emissions are stagnating

- Global demand for animal food is projected to increase (FAO)
- Global CH<sub>4</sub> emission from meat production will follow (FAO)

European emission trends (European Environment Agency)

CH<sub>4</sub> emissions from animal food products (FAO):

# Global atmospheric methane

## European emission trends (European Environment Agency)

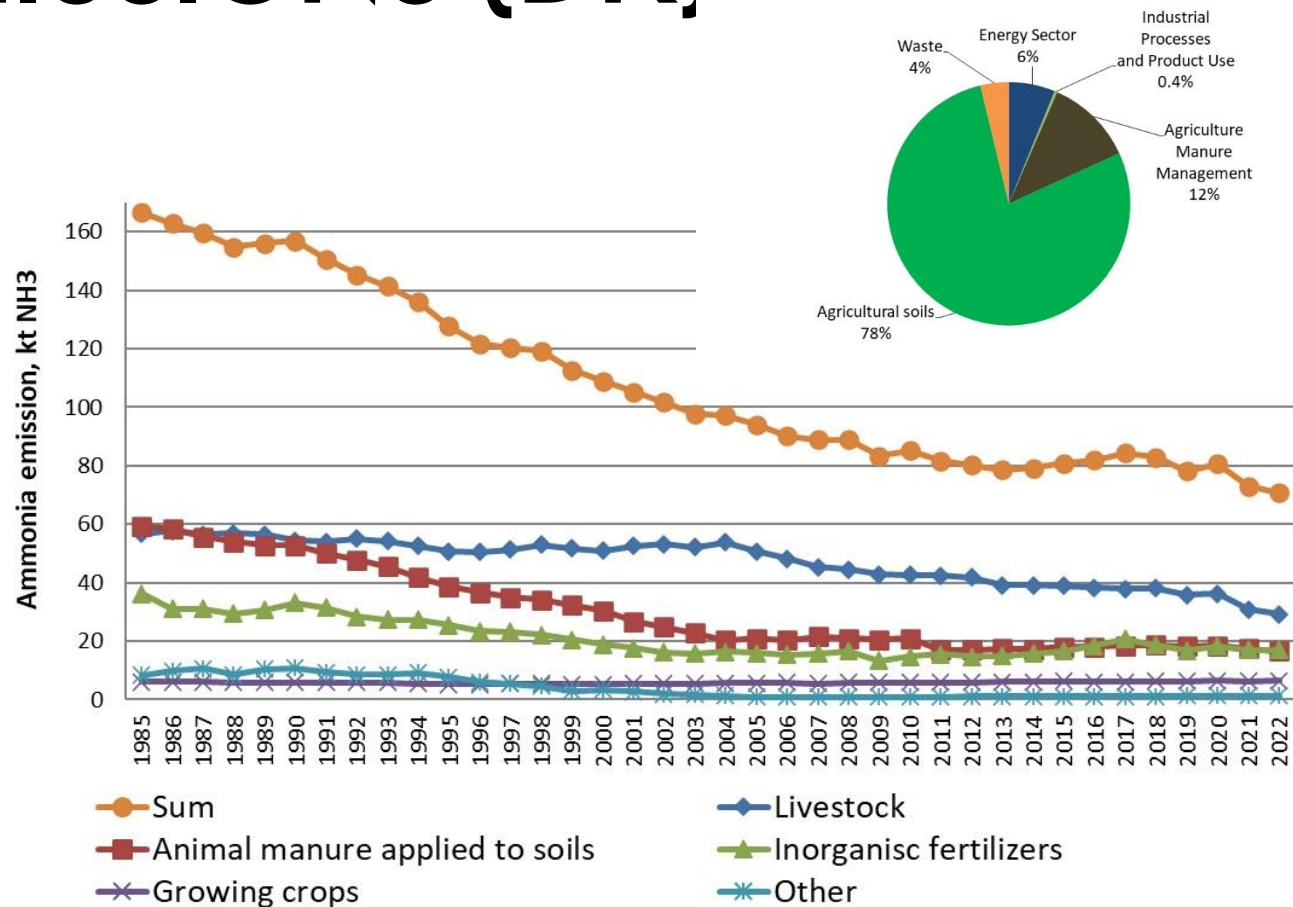

## Emissions from animal food products (FAO):

# LOCAL TRENDS IN EMISSIONS (DK)

- Data from DK national inventory

# EMISSION REDUCTION NEEDS/TARGETS

- NH<sub>3</sub> and VOC emissions are included in Gothenburg protocol

Agricultural GHG are part of e.g. EU target of emission reduction of 55% in 2030

Member States that meet their emission reduction commitments  
 Emission reduction by up to 10% of current levels needed  
 Emission reduction between 10% and less than 30% of current levels needed  
 Emission reduction between 30% and less than 50% of current levels needed

Limiting warming to 1.5°C at the lowest cost

By **2030**

methane emissions need to be reduced in each of the three main emitting sectors:

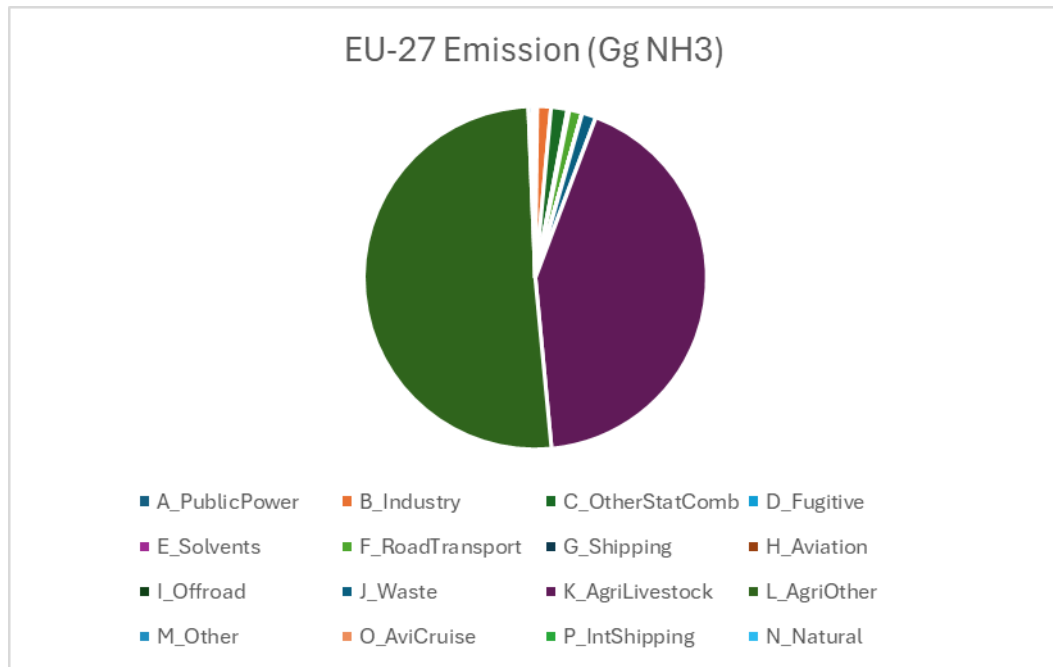

Reductions relative to 2020 emissions

# IMPORTANCE OF MANURE MANAGEMENT

- Manure management is by far the primary source of  $\text{NH}_3$  in EU
- Manure management is the second-largest source of  $\text{CH}_4$  in EU (after enteric  $\text{CH}_4$ )

# MANURE IN INTENSIVE LIVESTOCK SYSTEMS

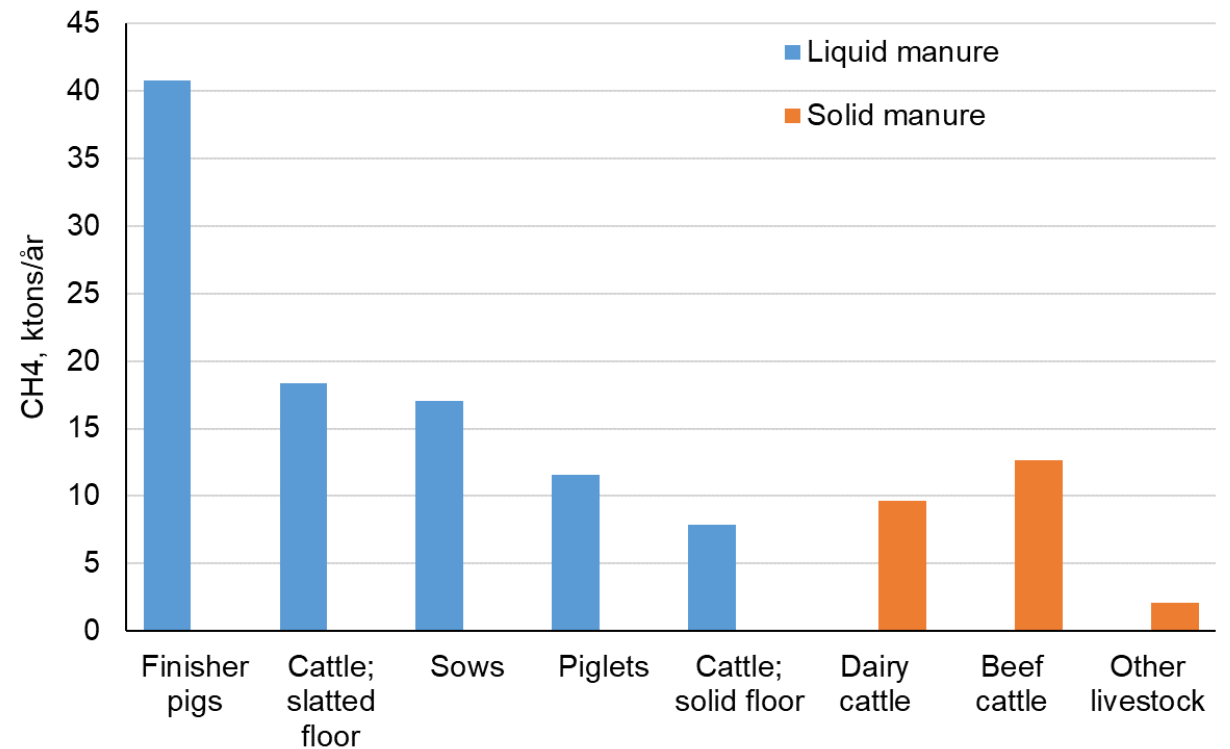

- Storage in-house and outdoor as liquid manure (slurry): Cattle and pig production
- GHG contribution **dominated by CH<sub>4</sub>** (90-95% of CO<sub>2eq</sub>)

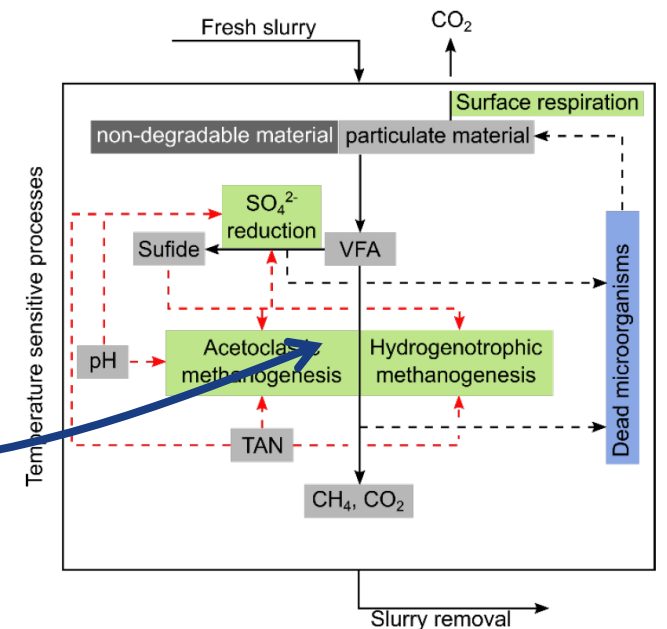

# SOLID MANURE CANNOT BE NEGLECTED

- Sources of CH<sub>4</sub> from manure management in Danish livestock production
- Data is extremely scarce, measurements are challenging
- In other countries, solid manure could have a bigger contribution

# REGULATION OF EMISSIONS IN DK

- Primary target towards 2030 : GHG emissions! But more data is needed!
  - Less attention on  $\text{NH}_3$  gas emission (N leaching and runoff is also high on the agenda)
- Current political negotiations concerning a GHG tax:
  - Suggestion: up to (!) 750 DKK (~100 Euro) per ton  $\text{CO}_{2\text{eq}}$
  - Requires detailed quantification of emissions at a farm level.
    - Incl all sources, mitigation strategies, feed variability etc.
- Farm level emission accounting does not exist today (for GHG)
  - It cannot be based on measurements alone  
→ models are needed, e.g. ABM

# THE ROLE OF MEASUREMENTS...

- Reliable measurements are needed for:
  - Model development
  - Model validation and calibration
  - Development of technologies
- Reference emission data for all important categories for:
  - Maintaining national emission inventories
  - Documentation of mitigation technologies and strategies
  - Checking modelled farm emissions

# MEASUREMENT CHALLENGES

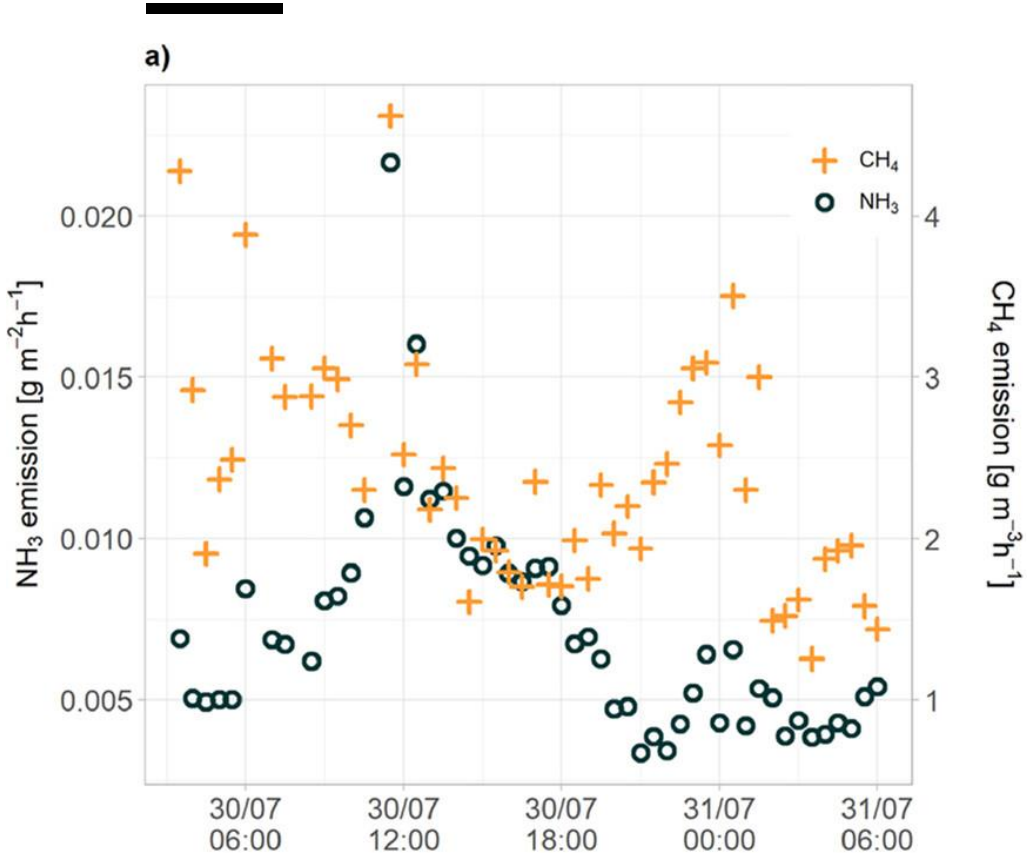

---

We need representative data which requires covering of:

- Short- and long-term temporal variations
- Spatial variability for e.g. area sources
- Farm-to-farm variability within a category
- Sources with complex geometry and natural ventilation
- Low emissions of e.g.  $\text{N}_2\text{O}$  and  $\text{NH}_3$   
= low  $\Delta\text{C}$

# TEMPORAL VARIATION (SLURRY TANKS)

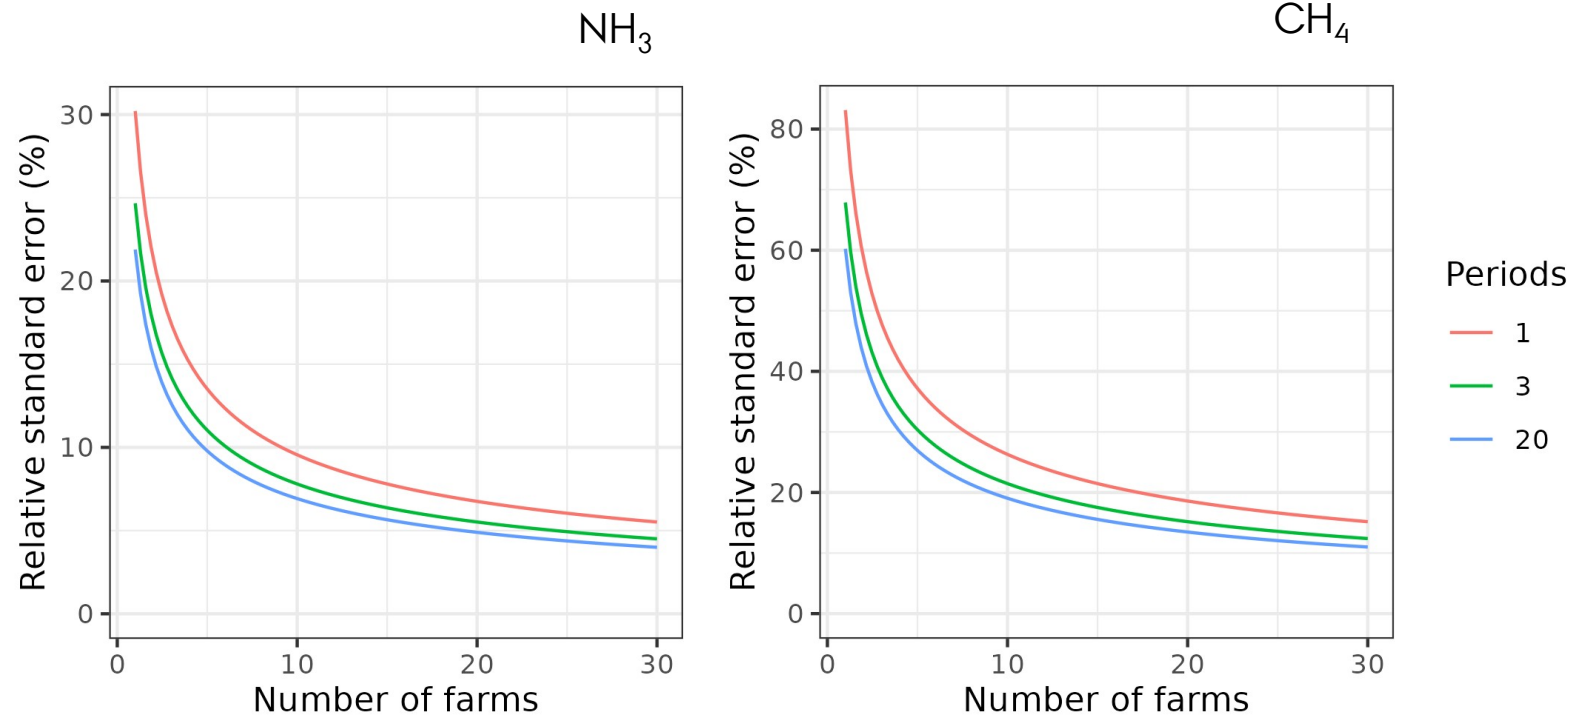

Lemes et al., 2022 AS&T

# FARM-TO-FARM VARIATIONS

Dairy cattle farms measured 6 times over one year.  
Error bars reflect annual variation.  
Kai et al., 2017

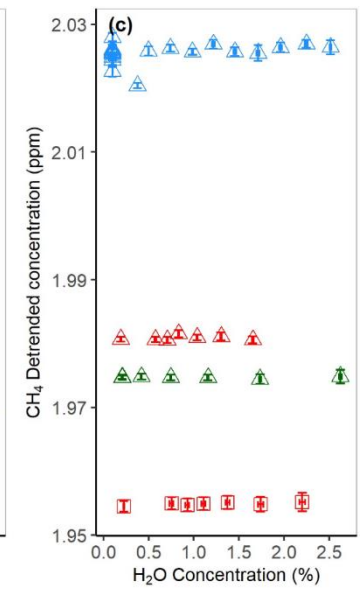

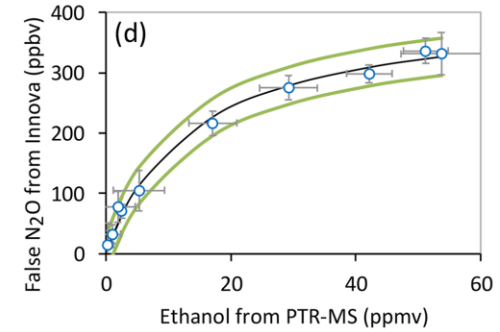

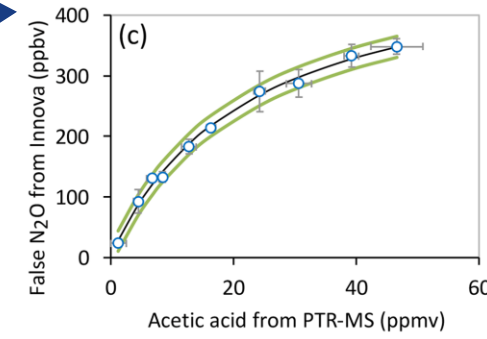

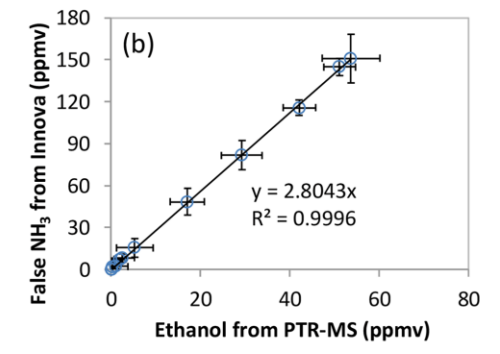

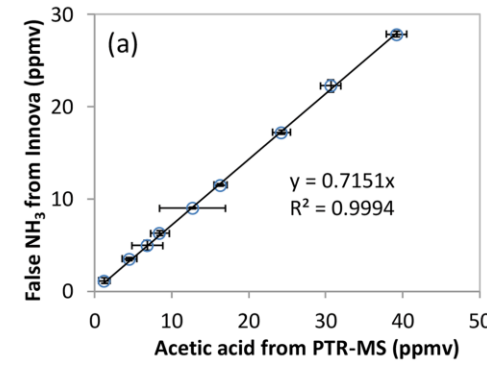

Relative error of emission data vs number of farms (pig facilities).  
Hafner & Dalby unpublished.

# SELECTION OF INSTRUMENTS 1

- Many gases are relevant to measure:
  - $\text{NH}_3$ ,  $\text{CH}_4$ ,  $\text{N}_2\text{O}$ ,  $\text{CO}_2$ ... VOC,  $\text{H}_2\text{S}$
- Sources are typically very complex
- Risk of interferences: Earlier data on agricultural emissions achieved with photoacoustic spectroscopy (PAS) using broad-range optical filters ☹️
  - With laser-based CRDS interferences are negligible except for extreme cases
- Concentrations (or  $\Delta C$ ) from few ppb to >100 ppm

G2509 □ G4301 ● Test 1 ● Test 2 ● Test 3\*

Garcia et al (2024) Under review.

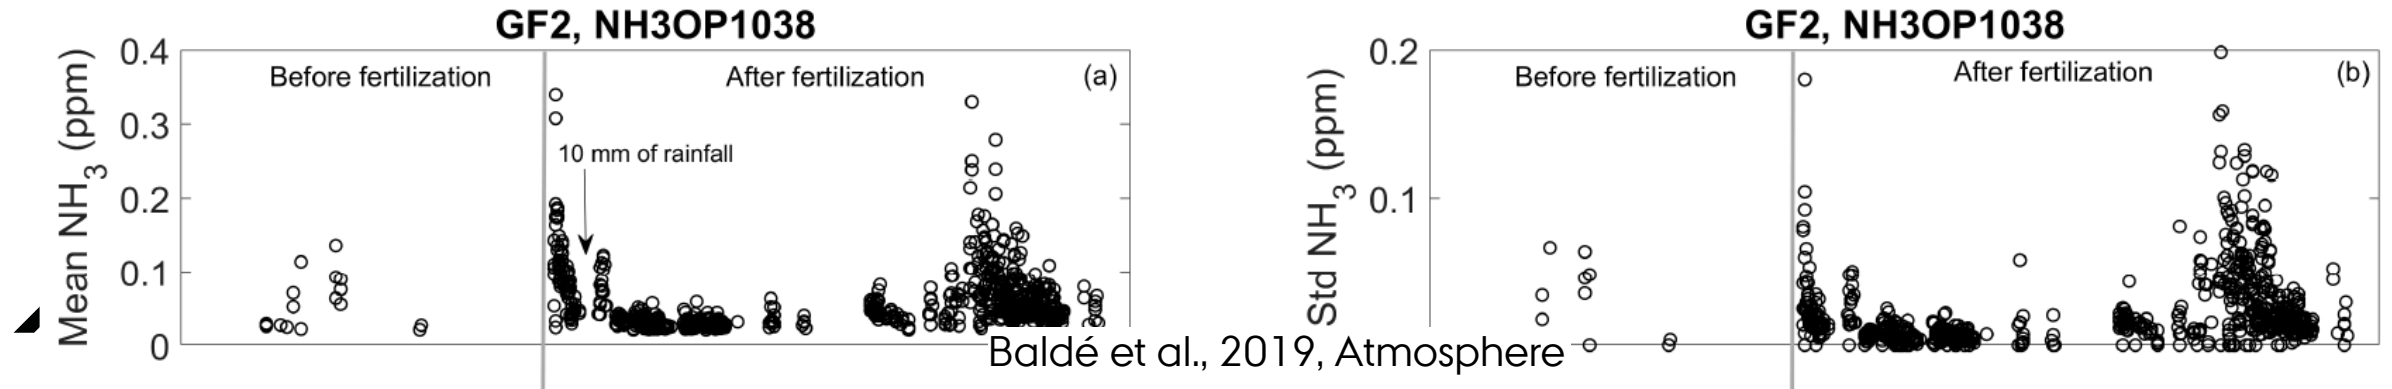

# SELECTION OF INSTRUMENTS 2

- We (AU) mainly have experience with closed-path measurement equipment (CRDS)
- For  $\text{NH}_3$ , heated sampling lines + high flow are needed to achieve high time resolution
- Open path alternatives:
  - Mini-DOAS ( $\text{NH}_3$ )  
not commercially available

- GasFinder ( $\text{NH}_3 + \text{CH}_4$ ) – appear to be not sufficiently sensitive at low concentrations

# PROTOCOLS

---

- Protocols (VERA or equivalent) exist for testing abatement technology for agriculture, but only cover  $\text{NH}_3$  and odor
- International protocols that include GHG are needed for:
  - Achieving representative reference data for regulation and national emission inventories
  - Testing of environmental technologies including GHG
- Protocols should cover:
  - Seasonal and diurnal variation
  - Source variability
  - Quality criteria for methods and instrumentation

# RELEVANCE OF AGRICULTURAL NMVOC

- NMVOC contributes to tropospheric ozone formation  $\Rightarrow$  accounting needed
- Recently updated emission estimates are available for agricultural sources

Data reported to CEIP/EMEP: <https://www.ceip.at/webdab-emission-database/reported-emissiondata>

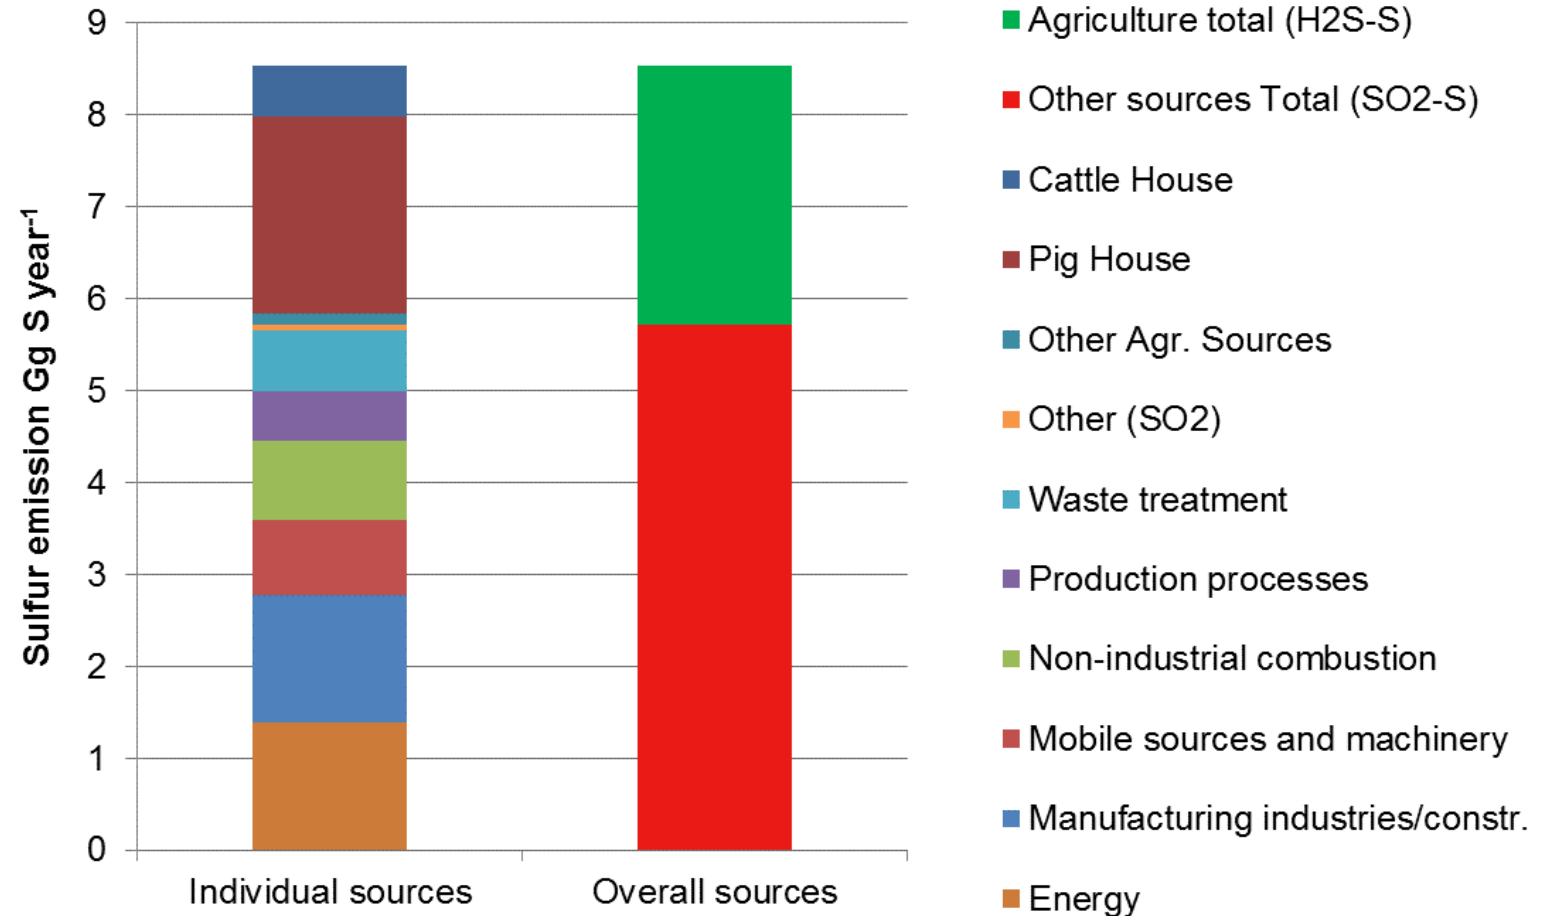

# SIGNIFICANCE OF LIVESTOCK H<sub>2</sub>S

Agricultural and other anthropogenic sources of sulfur in Denmark

# FUTURE RESEARCH NEEDS

---

- In general, a lot more data from relevant sources; systematic - unbiased - representative
- Measuring emissions from complex sources e.g.:
  - Farms with natural ventilation and access to outdoor yard
  - Grazing animals: low concentrations and high spatial/temporal variability
  - Includes also organic livestock farming
- Low-concentration emission sources of CH<sub>4</sub> and NH<sub>3</sub> e.g.:
  - Sources with efficient mitigation technologies (documentation)
  - Emissions from crops (NH<sub>3</sub>) and wetlands (CH<sub>4</sub>)
- Spatial and temporal variations in N<sub>2</sub>O emissions from agricultural fields
  - Small concentration differences!
